Subject: EPA ETS Classification

Tony,

As I understand the EPA decision re the "ETS as a Group A Carcinogen" classification, it based its decision on 11 US studies, and not on the 30 or 31 studies known worldwide.

My question: What would the result have looked like, if, with the same standards and confidence interval (90%) used for the EPA decision (based on 11 studies), all the 30 or 31 studies had been considered ?

I would appreciate receiving your explanation at your earliest convenience.

Kind regards,

Ulrich
